## 6. MECHANISATION

### 6.6 Mechanical sugarcane harvesting systems

**M**anual harvesting has dominated the industry, but it may become a less popular way of earning a living in the future. Many growers are therefore searching for a viable mechanical aid or mechanised system suited to local conditions.

Several imported whole stalk and combine chopper harvesters could not operate effectively on steep slopes, in recumbent cane and in fields not specifically prepared for mechanisation.

#### SEMI-MECHANISED SYSTEMS

In these systems, cutting, topping and trashing are done manually. The cane is placed in 3-6 ton stacks, or the cane from 4-6 rows is windrowed at right angles to the rows. The stacks are then winched onto tractor drawn trailers. The windrows are loaded by slewing or non-slewing loaders.

The cutting operation can be mechanised by using cutting attachments mounted on standard tractors, or small self-propelled walk-behind cutters.

#### Hand controlled self-propelled harvesters

These machines are suitable for small scale growers (less than 5000 tons) or for use in small fields. A range of 'walk behind' machines is available, equipped with a single base cutter and a chain driven windrowing attachment. The machines operate best on a flat culture but cannot handle recumbent cane, and are difficult to control on slopes.

#### Whole stalk linear windrowing harvesters

A single base cutter is usually mounted on the front of a tractor, to cut a single row in one pass (topping optional) and lay it down in a windrow. These are manually re-aligned into conventional windrows

made up of 4-6 rows, small 200-400 kg bundles or 3-6 ton stacks. The machines are able to cut both green and burnt cane, but do not remove any trash from the stalks.

Harvesting rates vary between 20 and 60 t/h, depending on cane yield, recumbency and whether the cane has been burnt. It is estimated that 20 of these harvesters have been sold in the industry. Twin base cutter models are also available.

#### FULLY MECHANISED SYSTEMS

##### Whole stalk transverse windrowing harvesters

**Tractor mounted.** The cutting/windrowing device is often three point mounted on the tractor. These machines cut one row of erect cane per pass, dropping the cane at right angles to the row. Before the next row can be cut the previously cut row has to be retrieved, topped and placed into bundles or a conventional windrow. In green cane the trash is removed manually.

*Grab loader operating in green cane.*

Harvesting rates vary widely depending on cane yield and terrain, but are not readily available.

**High capacity self-propelled.** This type of ‘soldier’ harvester was designed specifically for use in Louisiana and is suitable only for flat terrain. Single or two row machines cut and top green cane. The cut stalks are carried vertically by chain conveyor either through or along the side of the machines and are piled into windrows containing 3-6 rows of cane, leaving the tops in the interrow. The windrowed cane is burnt and then loaded by high capacity push-pile loaders into the infield transport. In most instances this consists of tractor/multiple basket trailer configurations.

Harvesting rates vary between 50 and 150 t/h.

#### **Whole stalk bundling harvesters**

**Chain conveyance bundle harvesters.** These are tractor drawn, tractor mounted or self-propelled machines, which top a single row with an external topper before the cane is cut by single or twin base cutters. The stalks are carried vertically through or along one side of the machine via a conveyor, and deposited horizontally in a collecting bin at the rear or side of the machine. Cane bundles can be dumped parallel or at right angles to the rows. Grab loaders load the bundles into the infield transport.

This type of machine does not operate successfully in recumbent cane. Harvesting rates vary between 15 and 40 t/h, depending on yield and the condition of the cane. Approximately 25 of these machines have been sold in the industry.

**Up-the-throat bundle harvesters.** These self-propelled, high capacity machines top the cane with an external topper and cut the cane using twin base cutters. The stalks are conveyed by feeder rollers and thrown into a bin at the rear of the machine. When the bin is full the bundles are dumped at intervals either parallel with or at right angles to the cane row. Grab loaders are used to load the bundles into the infield transport.

This type of harvester handles recumbent cane better than the chain conveying harvester. Single and two row machines are available. Harvesting rates vary between 20-40 t/h.

#### **Chopped cane combine harvesters**

**Whole stalk/chopped cane combine harvesters.** The front sections of these machines are similar to the Louisiana ‘soldier’ harvesters. After being base cut

**Bundle harvester operating in burnt cane.**

the cane is stripped of trash and cut into billets (or in the reverse order) before being conveyed by an elevator system and dumped into infield transport travelling next to the harvester.

Some of these are not commercially available at present.

**Up-the-throat chopper combine harvesters.** Most of these machines operate on the same principle. Stalks are topped by a hydraulically powered topper and then cut by twin base cutters. Rollers feed the cane into chopping blades which cut the stalks into 200-700 mm billets. A primary extractor fan removes much of the extraneous matter as the billets fall into the elevator hopper. From the hopper they are conveyed into the following transport. A second extractor fan at the top of the elevator assists in removing extraneous matter.

Many of these machines harvest cane in both directions on a single cutting face because they are equipped with slewing elevators. Combine harvesters can harvest cane in a wide range of conditions, from erect or recumbent to green or burnt. Harvesting rates can exceed 100 t/h. There are at least seven combine harvesters operating in the industry.

A comprehensive report, *A Review of International Cane Harvesting Machinery and Systems*, is available free of charge through your Extension Officer.
